A “Multimessenger” Approach to Substructure Lensing

Chuck Keeton

July 22, 2009

Substructure lensing

Past.

- ▶ Mao & Schneider 1998: connect **flux ratios** and substructure
- ▶ Metcalf & Madau 2001, Chiba 2002: propose to test CDM
- ▶ Dalal & Kochanek 2002: constrain **substructure mass fraction**

Present/future.

- ▶ New observables.
- ▶ Can we learn more about substructure?
- ▶ Is there really a **population of clumps**?
- ▶ Can we constrain its: **mass function**? **spatial distribution**?
redshift evolution?
- ▶ What does it reveal about dark matter?

Multiwavelength flux ratios

Heuristically, each wavelength probes substructure above some mass threshold:

$$\delta\mu(\lambda) \sim \int_{m(R_{\text{src}}(\lambda))}^{m_{\text{hi}}} m \frac{dN}{dm} dm$$

Plus, useful “resonance” if $R_{\text{ein}}(m) \approx R_{\text{src}}$.

Many possibilities:

- ▶ radio
- ▶ mid-IR (*Chiba et al. 2005, Poindexter et al. 2007, Minezaki et al. 2009, Fadely & CRK*)
- ▶ optical emission lines (*Moustakas & Metcalf 2003, Metcalf et al. 2004, CRK et al. 2006, Sluse et al. 2007, Sugai et al. 2007, Eigenbrod et al. 2008*)
- ▶ optical continuum
- ▶ X-ray (*Blackburne et al. 2006, Pooley et al. 2006, 2007, 2009, Kochanek et al. 2007, Morgan et al. 2008, Chartas et al. 2009, Dai et al. 2009*)

Lensing with stochastic substructure

Can we develop a general theory of substructure lensing?

1. Improve substructure modeling:

- ▶ faster
- ▶ richer — broader substructure models
- ▶ better — understanding of systematic uncertainties

2. Develop general insights:

- ▶ how is information about substructure encoded in lensing observables?
- ▶ what are the “reduced observables” we can/should aim to measure?

Framework

Lensing potential from 2-d Poisson equation:

$$\nabla^2 \phi = 2\kappa = 2 \frac{\Sigma}{\Sigma_{\text{crit}}}$$

Time delay:

$$\tau(\mathbf{x}; \mathbf{u}) = \frac{1 + z_l}{c} \frac{D_l D_s}{D_{ls}} \left[\frac{1}{2} |\mathbf{x} - \mathbf{u}|^2 - \phi(\mathbf{x}) \right]$$

Fermat's principle $\nabla_{\mathbf{x}} \tau = 0$ gives lens equation:

$$\mathbf{u} = \mathbf{x} - \boldsymbol{\alpha}(\mathbf{x}) \quad \text{where} \quad \boldsymbol{\alpha}(\mathbf{x}) = \nabla \phi(\mathbf{x})$$

Distortions/magnifications:

$$M = \left(\frac{\partial \mathbf{u}}{\partial \mathbf{x}} \right)^{-1} = \begin{bmatrix} 1 - \phi_{xx} & -\phi_{xy} \\ -\phi_{xy} & 1 - \phi_{yy} \end{bmatrix}^{-1}$$

Characterizing substructure effects

Can express observables in terms of

potential	ϕ
deflection	$\alpha_x = \frac{\partial \phi}{\partial x}$
	$\alpha_y = \frac{\partial \phi}{\partial y}$
convergence	$\kappa = \frac{1}{2} \left(\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} \right)$
shear	$\gamma_c = \frac{1}{2} \left(\frac{\partial^2 \phi}{\partial x^2} - \frac{\partial^2 \phi}{\partial y^2} \right)$
	$\gamma_s = \frac{\partial^2 \phi}{\partial x \partial y}$

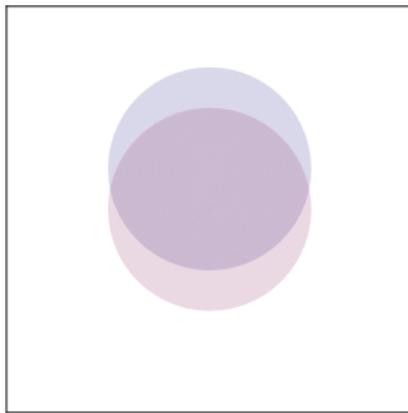

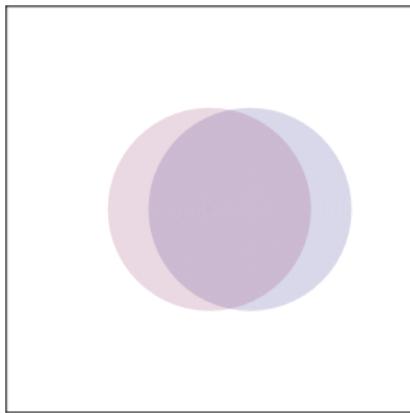

Formally, we need to know the (joint) probability distribution of $\Phi = \{\phi, \alpha_x, \alpha_y, \kappa, \gamma_c, \gamma_s\}$ at all image positions.

Use polar coordinates (r_i, θ_i) centered on an image:

$$\phi = \sum_i \frac{m_i}{\pi} \ln r_i$$

$$\begin{bmatrix} \alpha_x \\ \alpha_y \end{bmatrix} = - \sum_i \frac{m_i}{\pi r_i} \begin{bmatrix} \cos \theta_i \\ \sin \theta_i \end{bmatrix}$$

$$\begin{bmatrix} \gamma_c \\ \gamma_s \end{bmatrix} = - \sum_i \frac{m_i}{\pi r_i^2} \begin{bmatrix} \cos 2\theta_i \\ \sin 2\theta_i \end{bmatrix}$$

(Small corrections for any clump that overlaps line of sight.)

Can we just use the Central Limit Theorem?

No: variances diverge.

Trouble caused by clump(s) closest to image. If we can handle those, we can use CLT on the bulk of the remaining population.

Local analysis: Uniform spatial distribution

Goal: find probability distributions for most extreme shear, deflection, and potential.

Work through uniform case analytically for illustration.

$$p_x(\mathbf{x}) = \frac{\kappa_s}{N \langle m \rangle}$$

(Over some large but finite area such that $\int p_x(\mathbf{x}) d^2\mathbf{x} = 1$.)

Polar coordinates (r_i, θ_i) centered on an image. Shear strength:

$$\gamma_i = \frac{m_i}{\pi r_i^2}$$

What is the probability distribution for the largest shear?

Grav. imaging
Time delays
Recap

Theory
Framework
Local
Long-range
Local vs. total
Total

Complementarity

Outlook

Probability that the shear from clump i is bigger than γ :

$$\begin{aligned}
 P_i(>\gamma) &= \int_{\frac{m_i}{\pi r_i^2} > \gamma} p_x(\mathbf{x}_i) p_m(m_i) d^2\mathbf{x}_i dm_i \\
 &= \frac{1}{N \langle m \rangle} \int dm p_m(m) \int d\theta \int_0^{\left(\frac{m}{\pi\gamma}\right)^{1/2}} dr r \kappa_s \\
 &= \frac{1}{N \langle m \rangle} \int dm p_m(m) \times 2\pi \times \frac{1}{2} \left(\frac{m}{\pi\gamma}\right) \kappa_s \\
 &= \frac{\kappa_s}{N\gamma}
 \end{aligned}$$

Probability that *all* shears are smaller than γ :

$$P_{\text{all}}(<\gamma) = \left(1 - \frac{\kappa_s}{N\gamma}\right)^N \rightarrow \exp\left(-\frac{\kappa_s}{\gamma}\right) \quad \text{for } N \rightarrow \infty$$

This is the cumulative probability distribution for γ_{\max} .

Deflection strength:

$$\alpha_i = \frac{m_i}{\pi r_i}$$

What is the probability distribution for the largest deflection?

Probability that the deflection from clump i is bigger than α :

$$\begin{aligned} P_i(>\alpha) &= \int_{\frac{m_i}{\pi r_i} > \alpha} p_x(\mathbf{x}_i) p_m(m_i) d^2 \mathbf{x}_i dm_i \\ &= \frac{1}{N \langle m \rangle} \int dm p_m(m) \int d\theta \int_0^{\frac{m}{\pi \alpha}} dr r \kappa_s \\ &= \frac{\kappa_s}{N \pi \alpha^2} \frac{\langle m^2 \rangle}{\langle m \rangle} \end{aligned}$$

Probability that *all* deflections are smaller than α :

$$P_{\text{all}}(<\alpha) = \left(1 - \frac{\kappa_s}{N \pi \alpha^2} \frac{\langle m^2 \rangle}{\langle m \rangle}\right)^N \rightarrow \exp\left(-\frac{\kappa_s}{\pi \alpha^2} \frac{\langle m^2 \rangle}{\langle m \rangle}\right)$$

Long-range analysis

Can use Central Limit Theorem \Rightarrow need to know variance.

Illustrate with deflection:

$$\alpha_x = \sum_i \alpha_{xi}$$

Variance:

$$\begin{aligned}\text{var}(\alpha_x) &= \langle \alpha_x^2 \rangle - \langle \alpha_x \rangle^2 \\ &= \sum_i \sum_j \langle \alpha_{xi} \alpha_{xj} \rangle - \left(\sum_i \langle \alpha_{xi} \rangle \right)^2 \\ &= \sum_i \langle \alpha_{xi}^2 \rangle + \sum_i \sum_{j \neq i} \langle \alpha_{xi} \rangle \langle \alpha_{xj} \rangle - \left(N \langle \alpha_{xi} \rangle \right)^2 \\ &= N \langle \alpha_{xi}^2 \rangle - N \langle \alpha_{xi} \rangle^2\end{aligned}$$

Observables
Flux ratios
Multiwavelength
Milli-images
Grav. imaging
Time delays
Recap

Theory
Framework
Local
Long-range
Local vs. total
Total

Complementarity

Outlook

$$\begin{aligned}\langle \alpha_{xi} \rangle &= \frac{1}{N \langle m \rangle} \int dm_i p_m(m_i) \int d^2 \mathbf{x}_i \kappa_s(\mathbf{x}_i) \frac{m_i \cos \theta_i}{\pi r_i} \\ \langle \alpha_{xi}^2 \rangle &= \frac{1}{N \langle m \rangle} \int dm_i p_m(m_i) \int d^2 \mathbf{x}_i \kappa_s(\mathbf{x}_i) \left(\frac{m_i \cos \theta_i}{\pi r_i} \right)^2\end{aligned}$$

Note

$$N \langle \alpha_{xi} \rangle^2 \sim \mathcal{O} \left(\frac{1}{N} \right)$$

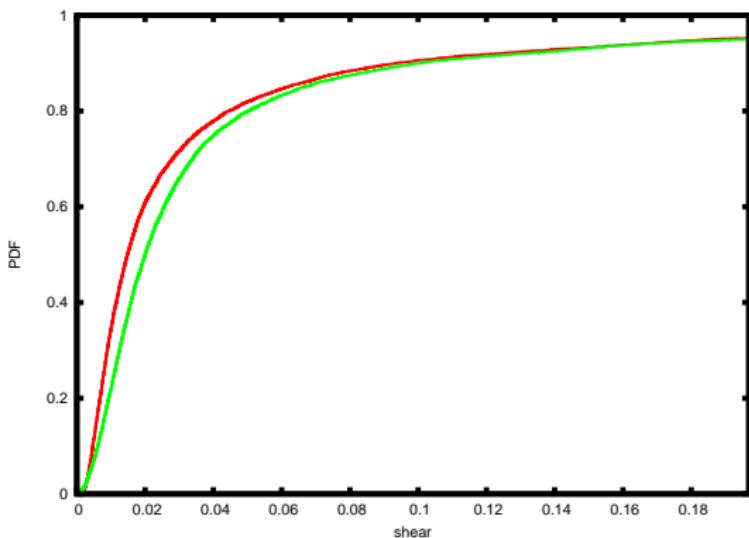

Thus

$$\text{var}(\alpha_x) \approx N \langle \alpha_{xi}^2 \rangle = \frac{\langle m^2 \rangle}{\langle m \rangle} \int d^2 \mathbf{x}_i \kappa_s(\mathbf{x}_i) \left(\frac{\cos \theta_i}{\pi r_i} \right)^2$$

Similar analysis for all quantities.

Mass function: Total shear

$\kappa_s \propto r^{-1}$ and $dN/dm \propto m^{-1.9}$.

Fix $m_{\text{eff}} = \langle m^2 \rangle / \langle m \rangle$. Vary $q = m_{\text{hi}}/m_{\text{lo}} = 1, 10, 100, 1000$.

Spatial distribution: Total shear

$\kappa_s \propto r^{\eta-2}$ and $dN/dm \propto m^{-1.9}$ with $q = 100$.

Isothermal ($\eta = 1$), steeper ($\eta = 0.5$), and shallower ($\eta = 1.5$).

Lensing Complementarity

Einstein radius, $R_{\text{ein}} \propto m^{1/2}$. Scaled distance, $\hat{r} = r/R_{\text{ein}}$.

observable	mnemonic	mass scale	spatial scale
magnifications	$\delta\mu \sim 1/\hat{r}^2$	$\int m \frac{dN}{dm} dm$	quasi-local
positions	$\delta x \sim R_{\text{ein}}/\hat{r}$	$\langle m^2 \rangle / \langle m \rangle$	intermediate
time delays	$\delta t \sim R_{\text{ein}}^2 \ln \hat{r}$	$\langle m^2 \rangle / \langle m \rangle$	long-range

Different observables contain different information about the clump population.

Outlook

Outlook

<i>what</i>	<i>how</i>	<i>reduced observables</i>
mass function	combine observables	$\int m (dN/dm) dm$ and $\langle m^2 \rangle / \langle m \rangle$
low-mass cutoff (e.g., WDM)	multiwavelength flux ratios	$\int m (dN/dm) dm$ for different thresholds
spatial distribution	time delays	something like $\int r^{-n} \kappa_s(\mathbf{x}) d^2\mathbf{x}$

Outlook

Outlook

Radio quads.

- ▶ radio loud: 9 — 3 currently have milli-images
- ▶ radio quiet: $\gtrsim 20$ — doable with EVLA and e-MERLIN?

(*N. Jackson, O. Wucknitz*)

Multiwavelength (optical/IR).

- ▶ Others: 4 quads + 1 double published
- ▶ Fadely: 1 quad + 5 doubles now, 2 quads + 8 doubles soon

Quad time delays. (*Congdon et al. ApJ submitted*)

- ▶ 7 known currently; more and better measurements to come...
- ▶ 1 with clear evidence for substructure
- ▶ 4 with “anomalies”

Gravitational imaging: $\gtrsim 100$ SLACS lenses. (*S. Vegetti et al.*)

Outlook

Outlook

Wide-field time-domain surveys will yield thousands of new lenses:
Pan-STARRS, DES, LSST, SKA, ...

Dream:

- ▶ Clean sample of ~ 100 quads.
- ▶ Radio/mid-IR photometry: **multiwavelength flux ratios**.
- ▶ Radio interferometry: **milli-images**.
- ▶ Optical/near-IR monitoring: **precise time delays**.
(Also microlensing and AGN structure.)
